**ABSTRACT**

Haemangiomas are defined as benign neoplasm arising from blood vessels, either in internal organs or in the skin. There are two types of haemangioma: capillary and cavernous. Capillary haemangioma is usually seen at the top layer while cavernous is often found at deeper layer. These are characterized by abnormal accumulation or growth of blood vessels filled with blood. The cavernous haemangiomas occur less frequently than the capillary ones. These are usually soft to touch. Although some haemangiomas involve large portion of body, most are localized. The majority of lesions are superficial, often of head and neck, but can occur internally. The internal organs mostly affected are liver, spleen, pancreas, GIT, skin, uterus and sometimes the brain. The cervical localization is low. Most of cervical haemangiomas are incidental findings and show asymptomatic behaviour. They sometimes may cause abnormal vaginal bleeding as menorrhagia, metrorrhagia or post coital bleeding and dyspareunia. The most common differential diagnosis include cervical malignant tumor. The treatment is the surgical excision.

**INTRODUCTION**

Haemangioma are benign neoplasm arising from blood vessels, either in internal organs or in the skin. There are two types of haemangioma: capillary and cavernous. The cavernous haemangioma occur less frequently than the capillary ones. The uterine cervix localization is very rare. Till date less than 50 cases have been reported. Most of cervical haemangioma are incidental findings and show asymptomatic behaviour. The most common differential diagnosis include cervical malignant tumor. The anatopathological study proves it benign and vascular nature. We present a case of 50 years old postmenopausal woman who reported in the outpatient department with history of infrequent episodes of bleeding for the duration of the last six months; the histopathology of which proved it to be the cavernous haemangioma. This cavernous haemangioma of cervix was clinically mimicking malignancy in view of its large size and polypoidal growth. The updated review of the literature is also being discussed (Table 1).

**CASE REPORT**

A 50 years old postmenopausal women present at our out-door patient department with complaints of episodes of infrequent episodes of painless bleeding for the last six months. She had normal menstrual history. She had four normal delivered and last child birth was 12 years back. Her physical examination and vital were unremarkable. Per speculum examination showed a spongy vascular growth having from the cervical region, fresh vaginal bleeding was present.
Per vaginal examination revealed uterus of normal size, firm, non-tender mobile with fornices free. A mass was felt arising from the endo-cervical canal. After routine investigation excisional biopsy was done and sent for histopathology. The post-operative period was uneventful. The histopathological analysis revealed cavernous haemangioma of cervix (Figure 1, 2 and 3).

**DISCUSSION**

Haemangiomas are very common tumors characterized by increased number of normal and abnormal vessels filled with blood and they are difficult to distinguish by vascular malformation. Uterine cervix cavernous haemangioma is a rare benign vascular tumor primarily superficial and/or deep dilated blood vessels. Other internal organs being affected are liver, spleen, pancreas, GIT, uterus, brain etc.²

Cavernous haemangioma differs from capillary in that they are less well circumscribed larger and deep in submucosal tissues. Less is known about the aetiopathogenesis of these mesenchymal tumors. According to Batsakis cavernous type is result of either a trauma or a congenital malformation. Hereditary factors may play a role in pathogenesis of some familial form of these tumors.³ Grey scale & Doppler shows a well-defined, uniformly hypoechoic lesion with peripheral feeder vessel which are pathogenesis of haemangioma.⁴

The Table 1 reports the cases of haemangioma associated with pregnancy, post coital bleeding or asymptomatic pathology. Like this case; the most of the reported cases presented with post coital bleeding. These lesions were suspected malignant clinically although cervical haemangioma are generally asymptomatic; 35% of cases presented as menometrorrhagia or post coital metrorrhagia. The age ranges from 12-52 years.⁷

Surgical excision is curative in most of the cases, but because of its haemorrhagic risk, conservative therapies have been suggested as sclerosing agents, cryotherapy, CO₂ laser excision. In order to preserve the fertility in young patients, local excision, conisation or laser ablation can done. Embolization treatment for A-V malformation was crowned in patients presenting with serious menorrhagia for symptomatic relief and to preserve reproduction. If necessary they can be treated by hysterectomy.⁸ Tanaka et al. reported spontaneous regression of the lesion.⁹

The diagnosis of cavernous haemangioma is histological. Histologically mass is shapely defined and not encapsulated and composed of large cavernous blood filled vascular spaces separated by modest connective tissue stroma. Intravascular thrombosis with associated dystrophic calcification is common. Histological differential diagnosis includes benign lesion having vascular component of reactional nature like pyogenic granulomas or botryomycosis granulomas. However its lobulated character and abundant inflammatory infiltrate favour most of a reactionary lesion.¹⁰

A few cases associated with pregnancy are reported. Changes during pregnancy under hormonal influences can cause obstetrical complication like premature rupture of membrane, premature labour, fetal death, Post-Partum Haemorrhage (PPH) and Disseminated Intravascular
Coagulation (DIC).\(^1\) Although delivery by natural way is possible but caesarean section is recommended to avoid serious consequences. Uterine atony or DIC can be observed which can lead to hysterectomy.

<td>9 unusual vascular tumors of the female genital tract and to investigate the problems in the differential diagnosis from other genital lesions. A capillary haemangioma of the endometrium, one capillary and one cavernous haemangioma of the cervix, 6 vulva lesions (one capillary, and one cavernous haemangioma and 4 angiookeratomas) and one haemangiosarcoma of the mons pubis in a 76-year-old patient were diagnosed. The differential diagnosis of the vascular tumors must be made mainly from endometriotic lesions and melanomas. Immunohistochemistry (S-100, CD31, CD34, CKS, EMA) aid in the Diagnosis. Local excision is appropriate for the benign vascular lesions.</td>

### CONCLUSION

Though uterine cervix cavernous haemangioma is a rare pathology, it may cause abnormal vaginal bleeding in the form of menometrorrhagia, post-coital bleeding or post-menopausal.\(^2\) Its differential diagnosis is difficult due to its rarity but one should always keep its possibility in a women proceeding with vaginal bleeding. The final diagnosis can only be made by histopathology.
